ABSTRACT
Methods for producing fibers of self-protonated sulfonic acid-substituted polyaniline compositions. The sulfonated polyaniline compositions have faster electronic and optical responses to electrochemical potentials comparing to its parent polyaniline, improved environmental stability, and improved solubility than the parent polymer, polyaniline.

PROCESS FOR FORMING FIBERS OF SULFONATED POLYANILINE COMPOSITIONS AND USES THEREOF

BACKGROUND OF THE INVENTION

The present invention is a continuation-in-part of co-pending application Ser. No. 07/423,902 filed Oct. 19, 1989 which is a continuation-in-part of co-pending application Ser. No. 193,946 filed May 13, 1988, now U.S. Pat. No. 45,079,334 which applications are expressly incorporated herein by reference.

The present invention relates to processes for forming fibers of self-protonated sulfonic acid-substituted polyaniline compositions and their derivatives and uses thereof.

Polyaniline is a family of polymers that has been under intensive study recently because the electronic and optical properties of the polymers can be modified through variations of either the number of protons, the number of electrons, or both. The polyaniline polymer can occur in several general forms including the so-called reduced form (leucoemeraldine base), possessing the general formula

\[
\left( \begin{array}{c}
\text{N} \\
\text{H} \\
\text{H} \\
\text{H} \\
\text{N} \\
\text{H} \\
\text{N} \\
\text{H} \\
\text{N} \\
\text{H} \\
\end{array} \right) 
\]

the partially oxidized so-called emeraldine base form, of the general formula

\[

\text{N} \\
\text{N} \\
\end{array} \right) 
\]

In practice, polyaniline generally exists as a mixture of the several forms with a general formula (I) of

\[
\left( \begin{array}{c}
\text{N} \\
\text{H} \\
\text{H} \\
\text{H} \\

\]

When \( 0 \leq y \leq 1 \), the polyaniline polymers are referred to as poly(paraphenylenamineimines) in which the oxidation state of the polymer continuously increases with decreasing value of \( y \). The fully reduced poly(paraphenylenamine) is referred to as leucoemeraldine, having the repeating units indicated above corresponding to a value of \( y = 1 \). The fully oxidized poly(paraphenylenimine) is referred to as pernigraniline, of repeat unit shown above corresponds to a value \( y = 0 \). The partly oxidized poly(paraphenylenimine) with \( y \) in the range of greater than or equal to 0.35 and less than or equal to 0.65 is termed emeraldine, though the name emeraldine is often focused on \( y \) equal to or approxi-
line can also then turned "off" by an opposite shift of the electrochemical potential.

The conductivity of polyaniline is known to span 12 orders of magnitude and to be sensitive to pH and other chemical parameters. It is well-known that the resistance of films of both the emeraldine base and 50% protonated emeraldine hydrochloride polymer decrease by a factor of approximately 3 to 4 when exposed to water vapor. The resistance increases only very slowly on removing the water vapor under dynamic vacuum.

The polyaniline polymer exhibits conductivities of approximately 1 to 20 Siemens per centimeter (S/cm) when approximately half of its nitrogen atoms are protonated. Electrically conductive polyaniline salts, such as fully protonated emeraldine salt \((\text{C}_6\text{H}_4\text{N}^+\text{Cl}^-\text{Li})\), have high conductivity \((10^{-4} \text{ to } 10^{-2} \text{ S/cm})\) and high dielectric constants \((20 \text{ to } 200)\) and have a dielectric loss tangent of from below 10\(^{-3}\) to approximately 10\(^1\). Dielectric loss values are obtained in the prior art by, for example, carbon filled polymers, but these losses are not as large nor as readily controlled as those observed for polyaniline.

The present invention is a continuation-in-part of and related to the invention disclosed in the co-pending application Ser. No. 70/423,902 filed Oct. 19, 1989 which is expressly incorporated herein by reference. That application discloses sulfonated polyaniline compositions and their derivatives, processes for their preparation and uses thereof.

While the preparation of polyaniline polymers and the protonated derivatives thereof is known in the art, it is novel to prepare sulfonated polyaniline compositions which are capable of being "self-protonated" or "self-doped". The use of the terms "self-protonated" and "self-doped" herein includes, but is not limited to, the reorganization of hydrogen ions on the polymer i.e., the absence of any counterion not covalently bonded to the polymer chain. For example, self-doping or self-protonation of a polyaniline base polymer leads to a polyaniline salt polymer and a reorganization of the electronic structure which then forms a polaronic metal. The conductivity of such polaronic metal is independent of external protonation.

It is known that most polymers consist of bonded carbon-to-carbon or carbon-nitrogen repeat units along the polymer backbone chain. While these kinds of chemical bonds are among the strongest bonds in nature, such strength is not often realized in most polymers since the polymer molecules exist primarily as entangled random coils.

It is further known that crystallization of polymers improves the strength and modulus of the polymers and improves the conductivity as well, by reducing the degree of molecular randomization and by increasing the coherence length of the polymer chain. While it is known that the drawing of polymers into continuous strands or fibers is one method of improving the crystallinity of the polymers, fiberization methods have, until now, not been feasible for producing fibers of sulfonated polyaniline polymers.

**SUMMARY OF THE INVENTION**

The present invention provides methods for producing fibers of a polymeric acid polymer which is capable of protonating or doping itself to form an electrically conducting polymer. The sulfonated polyaniline polymer has faster electronic, electrochemical, chemical, and optical responses and improved solubility than the parent polymer, polyaniline. The solubility of the sulfonated polyaniline polymer is increased greatly due to the presence of the sulfonic group \(\text{SO}_3\). The sulfonated polyaniline polymer is easy to dissolve in basic aqueous solutions in which the polyaniline polymer is insoluble. In addition, due to the electron withdrawing effects of the \(\text{SO}_3\) group, the sulfonated polyaniline polymer has improved environmental stability over the polyaniline polymer. The process for producing the sulfonated polyaniline comprises reacting the polyaniline polymer with fuming concentrated sulfuric acid or \(\text{SO}_3\) vapors.

The present invention also relates to the use of sulfonated polyaniline compositions and their derivatives in electronic, electrochemical, chemical, and optical applications.

According to the present invention, fibers of sulfonated polyaniline are formed by dissolving a sulfonated polyaniline composition either an acidic solution or a basic solution. A stream of the solution of dissolved sulfonated polyaniline is then drawn through a suitable dispersion medium whereby the sulfonated polyaniline composition coagulates in the dispersing medium. In one embodiment, the dissolving solution comprises sodium hydroxide and the coagulating medium comprises hydrochloric acid.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 is a schematic illustration of the different structures of sulfonated polyaniline, (a and b), the ammonia salt (c) and the emeraldine base (d).

**DETAILED DESCRIPTION OF THE INVENTION**

The present invention relates to processes for forming fibers of sulfonic acid substituted polyaniline compositions and their derivatives and uses thereof.

The self-protonated sulfonated polyaniline compositions have the formula I

![Formula I](image)

wherein \(0 \leq y \leq 1\); \(R_1, R_2, R_3, R_4, R_5\) and \(R_6\) are independently selected from the group consisting of \(\text{H}, -\text{SO}_3^-, -\text{SO}_2\text{H}, -\text{R-SO}_3\text{H}, -\text{R-OCH}_3, -\text{C}_6\text{H}_4\text{CH}_2\text{-F}, -\text{Cl}, -\text{Br}, -\text{I}, -\text{NR}_2\text{H}, -\text{NH-COR}, -\text{OH}, -\text{O}^-, -\text{SR}_2, -\text{OR}, -\text{OCOR}, -\text{NO}_2, -\text{COOH}, -\text{COOR}, -\text{COR}, -\text{CHO}\) and \(-\text{CN}\), wherein \(R_7\) is a \(\text{C}_1-\text{C}_8\) alkyl, aryl or aralkyl group. For the sake of clarity, the structure shown in formula I is in the non-self-protonated form.

The fraction of rings containing at least one \(R_1, R_2, R_3\) or \(R_4\) groups being an \(-\text{SO}_3^-\), \(-\text{SO}_2\text{H}\), \(-\text{R-SO}_3\text{H}\) or \(-\text{R}_2\text{SO}_3\text{H}\) can be varied from a few percent to one hundred percent. In certain embodiments the percentage ranges from at least approximately 20% up to and including 100%. It is within the contemplated scope of the present invention that the \(-\text{R}_2\text{SO}_3^-\) and \(-\text{R}_2\text{SO}_3\text{H}\) substituents can be varied so that the sulfonated...
polyaniline is soluble in a range of solvents in order to make the sulfonated polyaniline polymer more easily blendable with other polymers and/or more easily cast onto a variety of surfaces.

The solubility of sulfonated polyaniline can be varied by changing the degree of sulfonation (i.e., the sulfonation time and/or temperature in H₂SO₄(SO₃) or SO₃ or other sulfonation agents). It is noted that the oxidation state of the polymer (from leucoemeraldine through emeraldine to perrnigrilamine) and the degree of sulfonation (x) can be independently varied. Here x is the fraction of C=O rings which have an SO₃⁻ or SO₃H group attached.

When x=0, the polymer does not dissolve in either basic or acidic aqueous solutions. Upon increasing the value of x, the polymer becomes soluble in strongly basic, basic, weakly basic and eventually in acidic aqueous solutions. This progressive improvement in solubility implies that the polymer becomes soluble in neutral media, particularly H₂O, at the appropriate value of x, yielding a water-soluble conducting polymer. The color of soluble sulfonated polyaniline in acidic solution is green, indicating it is the conducting salt form.

The solubility of polyaniline is increased greatly in basic aqueous solution by the presence of -SO₃H group on the phenyl rings. This is in contrast with polyamine which when washed with basic solutions, converts to the insoluble base form.

Protonation of the emeraldine base polymer leads to the emeraldine salt polymer and a reorganization of the electronic structure to form a polaronic metal. Since benzenesulfonic acid is a strong acid, about as strong as hydrochloric acid, the sulfonated polyaniline is capable of conducting. Hence, the conductivity of the sulfonated polyaniline is independent of external protonation.

Being able to dope itself, the sulfonated polyaniline polymer has enhanced optical and electrical response to electrochemical potential as compared with the parent polyaniline polymer. Since the solid-state diffusion of counterions in and out of a polymer during electrochemical processes is often the rate controlling step in the kinetics, it also limits the speed of both optical and electrical response of polymers. In the self-doped conjugated polymer of the present invention, the counterions are not necessary from the medium. The positive charge introduced into the conjugated pi electron system of the backbone of the polymer is compensated by the protons behind the opposite charged counterion. Being the smallest and most mobile ion, proton hopping mechanisms lead to relatively fast doping kinetics as compared to those counterions migrating in or out of the polymer. As a consequence, it is possible to achieve sufficient speed to be useful for a variety of technological applications.

The sulfonated polyaniline polymers provide opportunities to use the phenomena of the dependence of electrical and optical properties on the backbone chain conformation and on the substituent as well as chain properties which change the chemical properties of polyaniline in a number of useful applications. The side groups on polyaniline also can affect the charge transport in polyaniline.

The chemical synthesis of the sulfonated polyaniline polymers of the present invention is accomplished by reacting polyaniline with concentrated or fuming sulfuric acid, gaseous SO₃, or other sulfonation agents. Examples of several of the methods for such synthesis are disclosed below.

Materials—Aniline and other chemicals were obtained from Aldrich and were all reagent grade or better. Hydrochloric acid and ammonium hydroxide were used as received. Different pH buffer solutions were commercially purchased.

For the sulfonation of polyaniline, 1.5 g polyaniline (dry emeraldine base form) was dissolved into 40 ml fuming sulfuric acid H₂SO₄(SO₃) with constant stirring at room temperature. During the sulfoozon period the color of the solution changed from dark purple to dark blue. After approximately 2 hours, the solution was slowly added during about 20 minutes to 200 ml methanol while maintaining the temperature between about 10°-20° C. by an ice bath. A green powder precipitate was formed during the mixing. After the mixing, 100 ml of less polar acetone was added to the solution in order to increase the precipitate. The green powder was then collected on a Buchner funnel using a water aspirator. The precipitate cake was washed portionwise (50 ml/portion) with methanol until the portion of the filtrate showed pH = 7 when tested by wet pH paper. The liquid level in the Buchner funnel was constantly adjusted so that it remained above the top of the precipitate. This prevented cracking of the precipitate cake, which would result in inefficient washing of the precipitate cake.

After the above washing, the precipitate remained under suction for approximately 10 minutes. It was then transferred to the filter paper to a vacuum desicator and dried under dynamic vacuum for 24 hours. Elemental analyses, as shown in Table I are consistent with the composition shown in FIG. 1 as structure a, compound I, which is sulfonated, protonated polyaniline in the emeraldine oxidative state. The self-doped polyaniline is readily dissolved in a dilute aqueous base solution to form a homogeneous blue-violet solution. The solubility of compound I in 0.1M NH₄OH and NaOH is about 23 mg/ml.

Chemical Synthesis II: 1.5 g polyamine (dry emeraldine base form) was dissolved into 40 ml concentrated sulfuric acid H$_2$SO$_4$ and the temperature slowly raised from the room temperature to 70° C., in water bath in 3 hour period with the constant stirring. The temperature was kept at 70° C. for 15 hours. Then the temperature was raised to 95° C. within 0.5 hour and kept there for 4 hours. The reaction mixture was cooled down to room temperature. The product was very slowly added to −38° C. ice made from 160 ml distilled H$_2$O in order to precipitate the polymer. The temperature of the solution was not allowed to reach higher than 0° C. during the process. After the temperature of the solution reached room temperature the solution was filtered to obtain a fine powder of sulfonated polyamine. Large particles were obtained by subsequently heating the room temperature solution up to 70° C. in a two hour period, then cooling to room temperature, and conducting filtration to separate the sulfonated polyamine from the solution. The sulfonated polyamine was washed with an excess of H$_2$O until the filtrate was neutral (as tested by pH paper). Dry sulfonated polyamine was obtained by pumping under dynamic vacuum at room temperature for 48 hours.

Chemical Synthesis III: From the Chemical Synthesis II described above a copolymer (i.e., the polymer mixture of polyamines and sulfonated polyamine) was obtained by partially sulfonating polyamine. This was done in exactly the same way described in the Chemical Synthesis II except utilizing shorter sulfonation times and/or lower sulfonation temperature.

Chemical Synthesis IV: Another way to prepare the copolymer polyamine-sulfonated polyamine was to react 2-amino benzene-sulfonic acid (2ASA) with oxidizing agent in the presence of aniline. 10 g (0.58 mol) 2ASA and 2 ml (0.02 mol) aniline were dissolved in 500 ml 1M HCl. A prepared solution of 6.609 g (0.029 mol) (NH$_4$)$_2$S$_2$O$_7$ in 200 ml 1M HCl was added dropwise to the monomer solution with vigorous stirring during a period of 10 minutes. After 1.5 hours, the precipitate was collected on a Buchner funnel. The precipitate was washed with 1M HCl until the filtrate was colorless. Then the precipitate was washed by 500 ml H$_2$O. To ensure that the copolymer was in its neutral form, the precipitate was then transferred into a beaker containing 500 ml of H$_2$O and stirred at room temperature for 4 hours. The mixture was filtered until the pH of the filtrate was 7. The dry copolymer was obtained by pumping under dynamic vacuum at room temperature for 48 hours.

Chemical Synthesis V: Another method for producing sulfonated polyamine comprises exposing the polyamine polymer to SO$_2$ gas, which method is fully discussed in co-pending application Ser. No. 07/529,024, filed May 25, 1990, entitled Processes For The Preparation Of Sulfonated Polyamine Compositions and Uses Thereof, which is expressly incorporated herein by reference. Conductivities of the compound 1 were measured on compressed pellets of the powder by using four point probe techniques with a Keithley 220 constant current source and Keithley 181 volt meter.

Conductivity studies are consistent with the sulfonation of emeraldine base with fuming sulfuric acid proceeding to give a self-doped, sulfonated, protonated forms of the emeraldine oxidative state of polyamine, the compound 1 which has a conductivity of about 0.1 S/cm. This polymer can be regarded as being formed by the hypothetically initial formation of the strong acid, shown as structure b in FIG. 1, which then immediately protonates the imine nitrogen atoms to give the conducting polymer in an entirely analogous manner to strong acids such as HCl. Treatment of the structure b compound with an aqueous (ammonium) base yields the sulfonated, non-protonated insulating ammonium salt forms analogous to emeraldine base, viz, the structure c compound shown in FIG. 1.

The conductivity of the compound 1 (σ ~0.1 S/cm) is similar to that of emeraldine hydrochloride measured under the same experimental conditions (σ ~1-1.5 S/cm, laboratory air), but lower than that of σ ~18 S/cm of high molecular weight emeraldine hydrochloride. The self-doped sulfonated polyamine with emeraldine oxidative state differs dramatically from nonexternally doped polyamine in conductivity. Since sulfonic acid is a strong acid, approximately as strong as hydrochloric acid, the compound 1 is capable of doping itself. Pressed pellets of the dark green self-doped compound 1 had a room temperature conductivity of about 0.1 S/cm in contrast to the purple color and insulating behavior of polyamine emeraldine base form. However, the conductivity of compound 1 is lower than that of emeraldine hydrochloride pressed pellets; analogy with earlier study of poly(o-toluidine), the lower conductivity is in accord with increased conduction electron localization induced by the side chain effects of −SO$_3$H. The solubility of the compound 1 also differs markedly from that of the corresponding polyamine polymer. The compound 1 dissolves completely in aqueous 0.1M NH$_4$OH or NaOH to give a blue-violet solution while polyamine washed with such solvent converts to the insoluble base form. The compound 1 partially dissolves in NMP to form a blue color solution and as well as DMSO (dimethyl sulfoxide) to show green color. The deprotonation results in a 5 to 10 order of magnitude decrease in conductivity. Compound 1 differs from emeraldine hydrochloride in that it is soluble in aqueous 0.1M NH$_4$OH and NaOH.

Elemental analyses and FTIR data suggest that, depending on the sulfonation times and temperatures, the number of −SO$_3$H groups per phenyl ring varied from 0.2 to 1.0. The conductivity is independent of pH in the range of pH values smaller than or equal to 7.

The sulfonated polyamine compositions and their derivatives are useful in electronic, electrochemical, chemical, and optical applications. The sulfonated polyamine compositions have a more rapid electro-
The chemical response than polyamine. The ability of the sulfonated polyamine compositions to have a fast switching speed between a conducting and a nonconducting state with good reversibility makes such compositions attractive polymers to use for a variety of electrochemical applications.

The sulfonated polyamine compositions and derivatives thereof have, or can be designed to have, desired processability in terms of, for example, viscosity, flexural strengths, solubility, adhesion to substrates, crosslinking, melting point, weight, adaptability to filler loading and the like. This is achieved by varying as desired the degree of self-protonation, the state of oxidation, and the type and degree of substituents on the polymer. Certain substituents may be preferred for the facilitation of desired processing parameters, such as increasing or decreasing solubility, altering extrusion parameters (rheology), achieving a specific viscosity, and the like.

The present invention provides a process for drawing sulfonated polyamine compositions into fibers. The sulfonated polyamine composition is dissolved in a suitable solution at a desired temperature until the solution is homogeneous. At least one stream of the homogeneous sulfonated polyamine polymer solution is attenuated or drawn into a continuous filament. The continuous filament is drawn through a dispersing or coagulating medium. It is contemplated that the continuous filament can be drawn by ejecting a vertical stream of the polymer solution into a reservoir of the coagulating medium. The fibers or filaments can then be collected in a conventional manner known to those skilled in the art. The coagulating medium thus contacts the stream of continuous filament as it is being formed or drawn, causing the sulfonated polyamine composition to coagulate or precipitate out of the homogeneous solution.

It is contemplated that the various methods available for producing a continuous filament having a relatively constant diameter can be employed with the fiber-forming method of the present invention. For example, the coagulating medium can be applied to the continuous filament in other such manners as, for example, being spray applied to the filament as it is being drawn.

According to the present invention, useful dissolving solutions include any suitable solvent for the sulfonated polyamine compositions. The solubility of the various sulfonated polyamine compositions is dependent upon the degree of sulfonation of the composition itself. The degree of sulfonation can generally be defined by referring again to formula 1 above, wherein the fraction of rings containing at least one R3, R2, R3 or R4 groups, wherein at least one of R1, R2, R3 or R4 is —SO3—, —SO2H, —R3SO3—, or —R3SO2H, varies from a few percent up to and including one hundred percent. Thus, examples of suitable dissolving solutions can comprise either acidic or basic solutions, such as concentrated H2SO4 or NaOH.

Further, according to the present invention, useful coagulating media include various compositions in which the sulfonated polyamine composition is essentially insoluble. The insolubility or degree of solubility of the sulfonated polyamine composition is dependent largely upon the degree of sulfonation and the type of R1, R2, R3, R4, R5 and R6 substituents as generally defined above, attached to the polyamine polymer. Thus, examples of suitable coagulating media can include, for example, water, methyl alcohol, ethyl alcohol, isopropyl alcohol, acidic aqueous solutions such as HCl, NaCl and the like, and various mixtures or combinations of any or all such coagulating media.

For the purposes of illustration only, various examples are given below. It should be understood that these examples are not limiting and that other methods of drawing or forming fibers of sulfonated polyamine compositions can also be utilized in the method of the present invention.

**EXAMPLE**

One method of drawing a fiber of a sulfonated polyamine composition comprises dissolving a predetermined quantity of a sulfonated polyamine polymer composition into concentrated sulfuric acid to about 10-15 wt. percent, and stirring at about room temperature until the solution was homogeneous. The polymer solution was transferred to a syringe with a needle having a 0.1 mm diameter. A stream of the polymer solution was steadily ejected into a 30 cm long, 1.5 cm wide vertical reservoir containing ethyl alcohol as the coagulating medium. As the sulfonated polyamine polymer falls due to the force of gravity, through the coagulating medium, a fiber is formed. With the temperature of the ethyl alcohol at about room temperature, a fiber of approximately 10 cm in length was formed. It should be understood that an increase in the viscosity of the polymer solution will aid in the fiber forming process.

**EXAMPLE**

Another especially suitable coagulating medium comprises methyl alcohol.

**EXAMPLE**

Another method for drawing a fiber comprises dissolving a predetermined quantity of a sulfonated polyamine composition in about 2-10 wt. percent of NaOH, and drawing the fiber in the manner described above wherein the coagulating medium comprises an acidic solution such as HCl.

The conductivity of the fibers formed according to the present invention, ranges from about 0.1 to about 1 S/cm, this showing that the fibers formed are made of a sulfonated polyamine composition.

Fibers produced according to the present invention can be used in any of the various application or contemplated uses disclosed in the parent co-pending application, Ser. No. 07/423,902 which application and uses disclosed therein are expressly incorporated herein by reference.

For example, it is contemplated that fibers of sulfonated polyamine compositions or derivatives thereof, or fibers of sulfonated polyamine copolymerized with another polymer can be drawn or extruded and subsequently woven into electromagnetic radiation absorbing fabric, garments, coverings, and the like. In this manner radar absorbing clothing can be produced.

Sulfonated polyamine absorbs electromagnetic radiation in the visible spectrum, in the infrared range, and in the ultraviolet range. Thus, fibers produced according to the present invention can be used to absorb infrared, visible, or ultraviolet waves comprising exposing the sulfonated polyamine to infrared, visible or ultraviolet waves, where the infrared, visible, or ultraviolet waves are absorbed by the sulfonated polyamine.

In addition, fibers produced according to the present invention can be used to absorb microwave radiation comprising exposing sulfonated polyamine to micro-
wave radiation, whereby the microwave radiation is absorbed by the sulfonated polyaniline; and for electromagnetic shielding.

It is further contemplated that fibers of sulfonated polyaniline compositions or derivatives thereof can be used as a fiber reinforcement material and be entrained in a matrix resin material.

While the invention has been disclosed in this patent application by reference to the details of preferred embodiments and examples of the invention, it is to be understood that this disclosure is intended in an illustrative rather than in a limiting sense, as it is contemplated that modifications will readily occur to those skilled in the art, within the spirit of the invention and the scope of the claims which follow.

We claim:
1. A method of producing at least one continuous filament of a sulfonated polyaniline composition having a chemical composition of formula I

wherein O ≤ y ≤ 1, R₁, R₂, R₃, R₄, R₅ and R₆ are independently selected from the group consisting of H, \(\text{SO}_3^+\), \(\text{SO}_2\text{H}^\cdot\), \(\text{R}_2\text{SO}_3^+\), \(\text{R}_2\text{SO}_3\text{H}^\cdot\), \(\text{OCH}_3\), \(\text{CH}_3\), \(\text{C}_2\text{H}_5\), \(\text{F}\), \(\text{Cl}\), \(\text{Br}\), \(\text{I}\), \(\text{NR}_2\text{H}^\cdot\), \(\text{NH}\cdot\text{COR}\), \(\text{OH}\), \(\text{O}^-\), \(\text{SR}_7\), \(\text{OR}_7\), \(\text{OCOR}_7\), \(\text{NO}_2\), \(\text{COOH}\), \(\text{COOR}_7\), \(\text{COR}_7\), \(\text{CHO}\) and \(\text{CN}\), wherein \(\text{R}_7\) is a \(\text{C}_1-\text{C}_8\) alkyl, aryl or aralkyl group, and wherein the fraction of rings containing at least one \(\text{R}_1\), \(\text{R}_2\), \(\text{R}_3\) or \(\text{R}_4\) group being an \(\text{SO}_3^-\).

5. The method of claim 1, in which the solution comprises the sulfonated polyaniline polymer and \(\text{H}_2\text{SO}_4\) and the precipitating medium comprises at least one of: water, methyl alcohol, ethyl alcohol, isopropyl alcohol, an acidic aqueous solution or an inorganic aqueous solution.

8. The method of claim 1, in which the solution comprises the sulfonated polyaniline composition and \(\text{NaOH}\), and the precipitating medium comprises \(\text{HCl}\).
