

Production DDU Design: Parts, Purpose and IO Usage

=====

Connections, Front Panel

15 fibers (input) from DMB

-Differential outputs from Fiber transceivers go directly to 2 Xilinx Virtex-2-Pro FPGAs (XC2VP20-6FG676c, 404 I/O each); these "InCtrl" FPGAs have 8 Rocket I/O each. The DMB-DDU fiber transmission is based on 80 MHz clocks provided by matched on-board oscillators on the DMB and DDU boards. The fiber connections are duplex, and the primary data direction is DMB-DDU, but the board is designed to support limited communication from DDU-DMB.

-Each InCtrl FPGA has 2 associated TI FIFO pairs (2 TI 74LV3690-6 FIFOs serially cascaded, 0.125 MB+ capacity each) operated with 18-bit in/36-bit out, Write clock @160MHz, Read clock @156MHz. LVCMOS 3.3V communication is used for the FIFOs.

-There are 2 separate Readout Control paths per InCtrl FPGA, with one Read Control path controlling its own TI FIFO pair.

-Logical Fiber Input Overview:

4 DMB Fibers ---> 1 Read Control ---> 1 TI FIFO pair

-Physical Fiber Input Overview:

7-8 DMB Fibers ---> 1 InCtrl FPGA ---> 2 TI FIFO pairs

1 fiber for Gigabit Ethernet (GbE) readout

-Driven by Rocket IO on the "DDUctrl" FPGA (XC2VP7-6FF672c, 396 I/O)

-The data for GbE packets is buffered in an on-board "Output FIFO" (IDT 72V72100, 72-in/18-out) prior to transmission. More below.

1 SLINK board for TF use

-Driven by DDUctrl FPGA, in parallel with Output FIFO input bus

-Has particular power and control requirements. More below.

1 FMM connector (RJ45 type)

-4 LVDS signals driven by "VMEctrl" FPGA (XC2V500-5FG456c, 264 I/O)

-Conforms to CMS TTS/FMM requirements. More below.

1 Block of 4 LEDs

-Green, orange, yellow and red LEDs are hard-wired to show 3.3V power, 2.5V power, FPGA Program_Done and VME DTACK respectively. The DTACK LED is driven by on-board discrete logic.

16 pairs of LEDs

-Each green/yellow LED pair is connected by light-pipes that correspond to its fiber connection. The green LED indicates a connected live channel (FOKout). The yellow LED flashes to show data activity (DAV) on the link.

-The 15 DMB Fiber LEDs are driven by InCtrl FPGA logic. The GbE LEDs are driven by DDUctrl FPGA logic.

Connections, Backplane

1 "standard" 5-row VME connector on P1

1 HSC connector for 3.2Gbs differential communication to DCC on custom P3

-2 differential High-Speed Connection paths per DDU, 3.12 Gb/s each
---> 620 MB/sec of real data throughput (due to 8b10b)

-These connectors also carry clock & control signals from the TTCrx mounted on the DCC.

Clocks and Distribution

156 MHz PECL on-board; goes to DDUctrl FPGA only. Used for DDU-DCC Gigabit Transceiver (GT) links (3.12Gb/s), and an internal DCM provides divide-by-2 for 78MHz TI FIFO control and data processing in DDUctrl. Data goes out to GbE FIFO and SLINK at 78MHz on a common bus, 64-bits wide (plus control signals).

80.00 MHz PECL on-board; drives a 1-5 PECL clock driver. 4 outputs to the InCtrl FPGAs & 1 output to VMEctrl, 1 load each.

62.5 MHz LVTTTL on-board; goes only to DDUctrl for GbE clocking
40.08 MHz LVTTTL LHC clock from TTC via DCC/backplane connection; DDUctrl FPGA serves as 1-3 clock driver with 1-output to each FPGA.
10 MHz LVTTTL SCLK (Serial/Slow Clock); derived from 80 MHz clock by DCM inside VMEctrl FPGA and fanned-out to All Other FPGAs and serial devices on a common bus (4 loads) with termination. Requires 24 mA IO drive setting.

FPGAs

XC2VP20 "InCtrl FPGAs" (need 2 for Input Control, use 254+ IO each)

-use FG676 package (404 I/O), -6 speed grade (faster -7 costs more)

-Two linked XC18V04 PROMS used to program both FPGAs in parallel

---> both InCtrl FPGAs use identical Firmware

-8 IO: use parallel load DIN[7:0] and CCLK line w/linked DONE pins

-set one FPGA as SelectMAP Master, other as SelectMAP Slave

---> SelectMAP Master provides program clock CCLK

-each FPGA uses 7-8 Rocket IO to read in 7-8 DMB fibers

-JTAG is used for all PROM programming via the VME FPGA; JTAG is available on all FPGAs for slow control

-Main Clock is 80.00 MHz DMB-DDU-matched oscillator (fanout from PECL clock driver)

---> drives 2 differential input pairs on InCtrl FPGA (4 BREF IO, not BREF2) for Fiber Reference clocks (1 Top edge, 1 Bottom edge) as well as logic clocks (via BUFG) and GT USRCLKs [GT is Gigabit Transceiver logic module from Virtex2 library]

Each InCtrl FPGA is functionally split into a "top half" and a "bottom half", each responsible for processing the data from the 4 top-edge RocketIO and 4 bottom-edge RocketIO respectively. Each half-FPGA has the following functions (see file ddu_in.pdf for logic schematics):

-44 Block RAMs configured as 22 FIFO MemUnits, 4 kB each, which are assigned to the RocketIO on an as-needed basis. In this way, any RocketIO that need more storage may be allotted any combination of the 22 MemUnits as they are available.

-A MemControl Unit to control assignment of the BRAM FIFOs. There is a priority algorithm to select the assignments preferentially.

-4 InUnits, each containing one RocketIO, a buffer to record MemUnits in use, and data monitoring logic. This logic watches for Status Codes sent from the DMBs and flags & corrects any 64-bit word boundary violations that occur. InUnits can also transmit data via fiber to any selected DMBs using a common data bus from the DDUctrl FPGA. Before the MemUnit in use becomes full, the InUnit will request another from MemCtrl, then switch to the new unit when the current one goes Full. InUnits will "free" a MemUnit for reuse when it goes Empty. Each InUnit has a 4-bit path to the VMEctrl FPGA to report status information.

-A ReadControl Unit that writes exclusively to one on-board TI FIFO pair (0.25 MB external storage). The RdCtrl gets the data from each RocketIO and checks L1A numbers for an event as the data is read out. RdCtrl forwards the Kill signal from DDUctrl to the appropriate RocketIOs and watches for timeouts or changes in the link status of the InUnits. It also monitors the AlmostFull/Full status of the external FIFOs and the internal MemCtrl, then sends out a Warning (to TTS) or Busy/Stop signal (to TTS & DMBs respectively) as needed. The event number and a summary of all the checks done within InCtrl are sent out to the FIFO as the last word of an event; this information will be assimilated in the DDUctrl FPGA. Each RdCtrl has a 4-bit path to the DDUctrl FPGA to report its operating conditions.

Both halves of the InCtrl FPGA share a common JTAG control unit. This is used primarily as an interactive monitoring/debug tool.

>>>InCtrl FPGA IO on-board hardware connections (for one chip):

4 dedicated input lines (2 pairs) from PECL clock driver

2 global Reset inputs (from DDUctrl)

1 LVTTTL clock input (SCLK) from VMEctrl

58 dedicated lines for TI FIFOs (50 Out, 8 In)

36 configurable IO to VMEctrl FPGA

59 configurable IO to DDUctrl FPGA
 24 IO for Fiber support (3 per fiber)
 70 Other IO, 12 required for parallel PROM load and INIT signals
 ---> optional 8 input from switches, 8 output to LEDs
 ---> optional 42 IO for header/testpoints for InCtrl FPGA#0
 ---> optional 6 IO for testpoints for InCtrl FPGA#1
 32 additional signals for RocketIO (4 per RocketIO)
 1 signal to specify chip as InCtrl FPGA#0 or #1

>>>How exactly do we use these IO in the DDU InCtrl?

-111 IO; each InCtrl FPGA uses these signals:
 80MHz Main Clock (4 IO), 40MHz LHC Clock (from DCC via DDUctrl
 FPGA), 10MHz SlowCLK from VMEctrl
 5-bits from DDUctrl: L1A, EvCntRst, L1RST, SoftReset, BC0/BXR
 13-bits to/from DDUctrl FPGA as spare (include 1 clock I/O pin)
 16-bits input data from DDUctrl for TxData to DMB (via Rocket IO)
 1 DLL Lock/Ready (to DDUctrl), 2 FIFO_Active (1 per RdCtrl)
 4 control/IO signals left free: INIT, CS, WRITE, DOUT (Don't Use)
 2 * 18-bit DOUT to FIFOs (bits 16-17 flag Fill/LW, Hdr/Tr)
 2 * 11-bit FIFO control: WCLK, ~WEN, ~PAE, ~PAF, FF, ~3/4Full
 SEN, SerLD, SerDat, Mode0, Model
 2 * 4-bit FPGA status bits (to DDUctrl, 1 4-bit set per RdCtrl)
 -72 IO; need per Rocket IO used on each FPGA (multiply below by 8):
 2-bits for Tx control from DDUctrl FPGA: TxEn, Kill Fiber
 3-bits for Fiber/FIFO Status: FOK (in), FOKout, DAV (to FP-LEDs)
 4 for DMB status: T[3:0] for FMM (to VMEctrl)
 -58 IO; added header connectors for 2 Logic Analyzer (LA) ports (18
 bits each, only InCtrl FPGA#0), 6 testpoints, 8 LEDs, 8 switches
 -8 IO dedicated for parallel PROM load
 -InCtrl FPGA#1 "kills" RocketIO #6 (the 16th RocketIO) as it is unused

XC2VP7 "DDUctrl FPGA" (uses 391+ I/O)

-use FF672 package (396 I/O), requires -6 speed grade or faster (-7)
 with flip-chip package
 -TWO linked XC18V04 PROMs, use parallel load DIN[7:0] and CCLK lines
 ---> use SelectMAP Master mode for program clock, FPGA drives CCLK
 -2 Rocket IO to backplane (data to DCC via HSC connector, 3.2 Gb/s)
 -1 Rocket IO to front panel output Gigabit Ethernet fiber (1.25 Gb/s)

The DDUctrl FPGA reads in data from the on-board TI FIFOs, 1 event at a time. Each event is checked for the following during readout:

-improper event formatting & data corruption
 -status/error flags passed from InCtrl via TI FIFO
 -event & bunch number synchronization from each source
 -CFEB wordcount & CRC from each source
 -DMB CRC & LCT/DAV consistency from each source
 -TMB wordcount & CRC from each source
 -ALCT wordcount & CRC from each source
 -missing DMB, CFEB, TMB or ALCT data from each source
 -Full and Near Full condition from each CSC
 -timeout conditions

DDUctrl performs the following tasks (logic schematics ddu_ctrl.pdf):

-event readout, processing and monitoring
 -receives & decodes TTC Command Bus instructions from DCC (via backplane); e.g. BC0, Sync/Soft Reset, Start/Stop data taking
 -receives & distributes CMS Clock & L1A from TTC/DCC to other FPGAs
 -watches for changes in status of the RdCtrl units
 -monitors the status feedback from the DCC/SLINK paths and Stops TI FIFO readout as needed
 -sends event information in the headers and trailers, conforming to CMS Common Data Format rules
 -generates a CRC word for all data transmitted for the event
 -sends all data out via DCC/SLINK paths
 -sends data to the external GbE FIFO on a prescalable basis
 -creates & transmits GbE packets from data stored in external GbE FIFO
 -reads Board ID & Killed Channel constants from Flash RAM and sends Kill Channel signals to InCtrl FPGAs

-controls a 16-bit data bus to send control or data signals out on any Fiber via InCtrl FPGAs
 -monitors the DDU Board Operation condition, summarizing the 4 RdCtrl and DDUctrl status on one 4-bit path to the VMEctrl FPGA for TTS

>>>DDUctrl FPGA IO on-board hardware connections:

3 dedicated input lines from PECL/LVTTL sources (4 IO)
 1 LVTTL clock input (SCLK) from VMEctrl
 2 IO for local 78 MHz LVTTL clock feedback
 2 global resets Out (Sync & Soft reset)
 18 control lines from TTC (15), DCC (2) & VME (1)
 72 dedicated lines for TI FIFOs (36 data, 36 control)
 96 configurable IO to InCtrl FPGAs
 19 configurable IO to VMEctrl FPGA
 116 IO for SLINK & GbE
 ---> Min. 83 for SLINK; 33 more are for GbE only.
 62 Other IO, 12 required for parallel PROM load and INIT signals
 ---> optional 8 input from switches, 8 PROM lines go to LEDs
 ---> optional 41 IO to header/testpoints, 1 pushbutton switch
 12 additional signals for RocketIO (4 per RocketIO)

>>>How exactly do we use these IO in DDUctrl?

-7 IO used for 4 ext. CLKs for DDUctrl: Main Clock (156 MHz) MUST use LVDS IO (IBUFGDS) & divide-by-2 for 78 MHz, one 62.5 MHz for GbE, 40.08 MHz LHC clock, 10 MHz serial shift clock (SCLK)
 ---> 78 MHz feedback LVTTL goes out * back for DCM lock (2 IO)
 -18 IO; DDU board control
 1 pushbutton input (debounced, goes to DDUctrl) used for logic RST
 1 SYSRESET input from VME, [+4 JTAG lines]
 3 DLL-Lock signals (1 from each FPGA, tells DDUctrl they're ready)
 4 FIFO_Active (1 per RdCtrl from InCtrl FPGAs)
 5-bits control output from DDUctrl, common for other FPGAs:
 L1Aout, EvCntRst, L1RST(SyncRst), SoftReset, BC0/BXR
 4 control/IO signals left free: CS, WRITE, DOUT, INIT (Don't Use)
 -30 IO; each InCtrl Rocket IO has individual controls (below times 15)
 Enable (for TxEn), Kill (for Rx/Tx)
 -16-bit output for DMB Tx data bus (parallel to both InCtrl FPGAs)
 -16 status bits from InCtrl FPGAs (4-bits from each RdCtrl)
 -26 bits from/to InCtrl FPGAs as spare (13 each, inc. 1 clock I/O pin)
 -38 IO; 1 36-bit input data bus to read 4 TI FIFO pairs,
 plus 2 RCLK signals shared by the TI FIFOs (2 loads each)
 -32 IO; each TI FIFO pair has individual controls (mult. by 4 below):
 ~OE, ~REN, EF, ~HF, ~PAF, FF, TransferWEN, TransferCLK
 -2 IO; common FIFO control (for all TI FIFOs):
 ~MRST (after soft reset), ~PRST (after sync/logic reset)
 -16 IO; control input from TTC/DCC
 cmd_bus[8:0], L1A, Link Ready/Full, plus 4 others
 -66-bit output data (to GbE FIFO/SLINK)
 -18-bit input data from GbE FIFO (for GbE packets out via RocketIO)
 -12 IO; GbE FIFO control (SDR IDT Supersync):
 WCLK, RCLK, WEN, REN, FF, ~PAF, ~PAE, MT, ~HF
 Output fiber FOK, FOKout LED, DataValid LED
 -18 IO; SLINK control
 10 Inputs: LFF, LDOWN, LRL[3:0], LSF[3:0]
 8 Outputs: UWEN, UCTRL, URST, UTEST, USF[3:0]
 -19 IO; communication to/from VMEctrl
 4 FMM bits to VMEctrl
 4 FMM bits from VMEctrl (also go to FMM cable)
 2 control bits for SLoad, SData input from VMEctrl
 -from serial-flash memory for "kill" fiber [16],
 Board ID [32], etc.
 9 bits from/to VMEctrl FPGA as spare (includes 1 clock I/O pin)
 -57 other IO; 8 switches, 8 LEDs (share PROM DIN), 2 LA Ports (36 IO),
 5 extra IO to "test points"

XC2V500-5FG456c "VMEctrl FPGA" (uses 264 IO)
 -One XC18V04 PROM, use parallel load DIN[7:0] and CCLK lines
 ---> use SelectMAP Master mode for program clock
 -Program VME PROM from VME FPGA, JTAG cable or Discrete on-board
 VME Logic; uses parallel load DIN[7:0] and CCLK lines to FPGA
 -Main Clock is 80.00 MHz DMB-DDU-matched oscillator (fanout from PECL
 clock driver)

VMEctrl performs the following tasks (logic schematics ddu_vme.pdf):
 -decodes VME Bus signals into on-board Parallel, Serial and JTAG paths
 -controls all Read and Write functions for the on-board 1 Mb Serial
 Flash RAM; constants are read out and sent to the appropriate
 devices after every Soft Reset
 -continually receives 4-bit status summaries from DDUctrl and 15 fiber
 sources, uses this to determine the instantaneous status of the
 entire 20-degree DDU Sector, sending the result to TTS via FMM

>>>VMEctrl FPGA IO on-board hardware connections:
 2 dedicated clock input lines from PECL clock driver
 2 global resets In (Sync & Soft reset from DDUctrl)
 15 configurable IO to DDUctrl FPGA
 68 configurable IO from InCtrl FPGAs
 67 dedicated lines for VME Backplane IO
 4 dedicated output lines to RJ45 for FMM/TTS; LVTTTL-LVDS
 conversion done on-board
 32 IO for 8 JTAG paths (for FPGAs, PROMS & FIFOs)
 13 IO for other Serial controls (FIFO threshold, etc. from SRAM)
 59 Other IO, 12 required for parallel PROM load and INIT signals
 ---> optional 8 input from switches, 8 PROM lines go to LEDs
 ---> optional 39 IO for header/testpoints

>>>How exactly do we use these IO in VMEctrl?
 -47 VME input IO: ADR[23:1], AM[5:0], GA[5:0], IRQ1, IackIN,
 sysreset, sysfail, clk, write, iack, lword, berr, as, ds0, dsl
 -20 VME output IO: dtack, ToVME, doe, D[15:0], IackOUT
 -70 FMM IO: 4-bit FMM output (to DDUctrl [TTL] and FMM cable [LVDS]),
 60-bit DMB status input (15 DMBS * 4 bits each from InCtrl FPGAs),
 4-bit DDUctrl status inputs, 2 LEDs
 -9 control IO
 80 MHz PECL clock, 2 global Reset inputs (from DDUctrl)
 1 DLL Lock/Ready (to DDUctrl)
 4 control/IO signals left free: CS, WRITE, DOUT, INIT
 -14 Serial control IO (for 4 Input FIFOs, 1 Output FIFO, 1 DDUctrl)
 Common SCLK (4 loads), SData (2 loads), 1 FIFO_SEN,
 6 bits for FlashMemory Control (M_SCLK, SI, SO, ~CS, ~WP, ~RESET)
 4 bits for SerADC Control (ADCclk, ADCdin, ADCsel, ADCout),
 1 Serial Enable bit to DDUctrl
 -9 spare signals to DDUctrl FPGA
 -8 spare signals to InCtrl FPGAs
 -32 IO for 8 JTAG paths (4 IO each):
 1 for DDUctrl PROM
 1 for DDUctrl FPGA
 1 for VMEctrl PROM (program by VMEctrl, VME-Recovery & JTAG cable)
 2 for InCtrl FPGAs (1 each)
 1 for InCtrl PROMs (in series, matched with DONE/PROGRAM order)
 1 for S-Link
 1 for output FIFO
 -55 other IO: 8 switches, 8 LEDs (share PROM DIN), 2 LA Ports (36 IO),
 3 extra IO to "test points"

FIFOs & on-board Flash Memory

Input FIFO: use 8 TI 74LV3690-6 (128 PQFP, 32K x 36-bits)
 -FIFOs are paired for a combined depth of 64K
 > first FIFO: 18-bits In (160MHz), 36-bits Out (156MHz)
 > second FIFO: 36-bits In (156MHz), 36-bits Out (156MHz)
 Output FIFO: use IDT 72V72100 (256 PBGA, 64K x 72-bits, 72/18)

-use 66-bits In (78MHz), 18-bits Out (62.5MHz)
 Serial Flash RAM: use 1 AT45DB011B (over 1 Mb, 8-pin SOIC), 20 MHz max.
 -uses 10 MHz derived from SCLK; can do 20 MHz, but the GbE FIFO
 serial clock is limited to 10 MHz max.
 -stores constants in Pages for DDU Board ID, Killed channels, etc.
 Useful OpCodes: d2h, d7h, 82h
 -all constants only use ~100 bits of memory; over 1 Mb is available
 for additional constants if desired
 Use Block0: page1=KillCh (16b), page7=BoardID (8b),
 page4=free (32b), page5=GbE FIFO Thresh (34b)

Other Notes

 Hard_Reset has 3 sources logical OR'ed together w/discrete on-board logic:
 -TTC via DCC/Backplane connection
 -Power-On sensor
 -PROGRAM button input (debounced)
 Hard_Reset goes to all FPGA PROGRAM pins.
 The 2nd on-board pushbutton (debounced) makes a Soft_Reset in DDUctrl,
 which fans it out to other FPGAs, and sends sync'd MRST to all
 FIFOs. (This could be reconfigured for another purpose as needed.)
 -VMEctrl sets the LD & FWFT/SI signals in time with the MRST
 The board has discrete "Emergency VME-Recovery" logic on board to allow
 for bootstrap VMEctrl PROM programming. There is also a 10-pin JTAG
 header connector for programming this PROM via laptop if desired. All
 other PROMs _must_ be programmed via VME, with no alternative provided.

=====
 The 3 sections below are the UCF files containing the Location and Timing
 Constraints for all FPGA firmware.

#
## VIRTEX 2 Geometry Summary (XC2VP20-FG676):
# 4 Slices per CLB, 2 TBUFs per CLB
# 2 LUTs per Slice, 2 FDs per Slice (share common RST/CE/CLK)
# 2 Fast Carry MUXCYs per Slice, plus 1 Fast ORCY
# 1 MUXF5 and 1 MUXF6 per Slice (x=6,7 or 8)
#
# For "Normal" Coords (x,y) Slices, TBUFs, RAMBs, etc all have
# independent coordinate origins, so use GRID coords if
# you must combine different types of components.
# Component coordinate ranges:
# SLICE x0y0 to x9y111
# TBUF x0y0 to x90y111, even x only
# RAMB16 x0y0 to x7y13 (88 total)
# GT x0y0 to x3y1 (8 total)
# DCM x0y0 to x3y1 (8 total)
# MULT18X18 x0y0 to x7y13 (88 total)
#
# In GRID Coords (X,Y) bottom left is X3Y4, top right is X138Y227
# X value cycles through SLICE-TBUF-SPECIAL with increasing X
# -X3Y4 is a SLICE, so is X138Y227
# -SPECIAL is RAMB/MULT or GT or DCM
# -SPECIAL only exists at X=8,26,44,62,80,98,116,134
# RAMB/MULT exist at all these X locations
# GTs at X=26,62,80,116 .and. Y=19,227
# DCMs at X=8,44,98,134 .and. Y=3,231
# Y values are continuous for Slices, except for PPC holes
# -TBUFs are only even in Y (2 per CLB)
# -RAMBs are spaced 16 apart in Y,
# starting at Y=35 on GT columns, Y=19 otherwise
# (GTs effectively take up a RAMB spot)
# -MULTs are 1 lower in Y than RAMB (at Y_RAMB - 1)
# PPC "Dead Zone" holes:
# No TBUFs from x14y40 to x58y71 .and. x62y40 to x76y71
# GRID: X23Y88 to X47Y143 .and. X95Y88 to X119Y143

#
# FCKIN -> CLK156 comes from 156MHz oscillator, goes to FD to drive CLK78;
# these are used to drive CKFB_OUT (78MHz, 1 load to FPGA:CKFB_IN, Slow
# 8mA) and IRCLK0/1 (156MHz, 2 loads each to InFIFOs, Fast 24/16mA).
# CKFB_OUT is phase-delayed by ~1.7ns due to Drive settings, but IRCLKs
# get delayed up to 0.5ns due to extra loads, so:
# at the pins, CKFB_IN is slower than IRCLKs by 1.2-1.6ns
# Roundtrip time to FIFO is 0.3-0.6ns, and this can be absorbed into the
# clock delays such that
# **effectively, CKFB_IN is slower than IRCLKs 0.6 - 1.3ns **
# This matches well with the FIFO RCLK-to-Output lag of 2-4.5ns.
# Meas'd FIFO RCLK-to-Output lag=2.5-3.6ns for Empty, 2.5-4.3ns for Data.
# Note that (CKFB_IN -> CLK/FCLK) has an IBUF delay and so does FIFO Data,
# so the IBUF delays CANCEL OUT: check constraints for double-counting.
# Constraints need only use Effective CKFB lag & FIFO RCLK-to-Output lag.
#
