DDU 2004 Design: Parts, Purpose and IO Usage

Connections, Front Panel

- 15 fibers (input) from DMB
 - -Differential outputs from Fiber transceivers go directly to 2 Xilinx Virtex-2-Pro FPGAs (XC2VP20-6FG676c, 404 I/O each); these "InCtrl" FPGAs have 8 Rocket I/O each. The DMB-DDU fiber transmission is based on 80 MHz clocks provided by matched on-board oscillators on the DMB and DDU boards. The fiber connections are duplex, and the primary data direction is DMB-DDU, but the board is designed to support limited communication from DDU-DMB.
 - -Each InCtrl FPGA has 2 associated Terasync FIFOs (IDT72T40118L5BB, 0.5 MB+ capacity) operated with 20-bit in/40-bit out using DDR clocking, Write clock @80MHz, Read clock @78MHz. LVCMOS 2.5V communication is used for the FIFOs.
 - -There are 2 separate Readout Control paths per InCtrl FPGA, with one Read Control path controlling its own Terasync FIFO.
 - -Logical Fiber Input Overview:
 - 1 Terasync FIFO <--- 1 Read Control <--- 4 DMB Fibers
 - -Physical Fiber Input Overview:
 - 2 Terasync FIFOs <--- 1 InCtrl FPGA <--- 7-8 DMB Fibers
- 1 fiber for Gigabit Ethernet (GbE) readout
 - -Driven by Rocket IO on the "DDUctrl" FPGA (XC2VP7-6FF672c, 396 I/O) -The data for GbE packets is buffered in an on-board "Output FIFO" (IDT72T72115L5BB, 72-in/18-out) prior to transmission. More below.
- 1 SLINK board for TF use
 - -Driven by DDUctrl FPGA, in parallel with Output FIFO input bus -Has particular power and control requirements. More below.
- 1 FMM connector (RJ45 type)
 - -4 LVDS signals driven by "VMEctrl" FPGA (XC2V500-5FG456c, 264 I/O) -Conforms to CMS TTS/FMM requirements. More below.
- 1 Block of 4 LEDs
 - -Green, orange, yellow and red LEDs are hard-wired to show 3.3V power, 2.5V power, FPGA Program_Done and VME DTACK respectively. The DTACK LED is driven by on-board discrete logic.
- 16 pairs of LEDs
 - -Each green/yellow LED pair is connected by light-pipes that correspond to its fiber connection. The green LED indicates a connected live channel (FOKout). The yellow LED flashes to show data activity (DAV) on the link.
 - -The 15 DMB Fiber LEDs are driven by InCtrl FPGA logic. The GbE LEDs are driven by DDUctrl FPGA logic.

Connections, Backplane

- 1 "standard" 5-row VME connector on P1
- 1 CCB connector (125 pin) on "P2" for TF DDU version only!
 - -Z type, # pins?
 - -FPGA signal connections?
- 1 HSC connector for 3.2Gbs differential communication to DCC on custom P3
 -NOT used on TF DDU version!
 - -2 differential High-Speed Connection paths per DDU, 3.2 GB/s each ---> 640 MB/sec of real data throughput (due to 8b10b)
 - -These connectors also carry clock & control signals from the TTCrx mounted on the DCC.

Clocks and Distribution

156 MHz PECL on-board; goes to DDUctrl FPGA only. Used for DDU-DCC Gigabit Transceiver (GT) links (3.2Gb/s), and an internal DCM provides divide-by-2 for 78MHz DDR FIFO readout and data

- processing in DDUctrl. Data goes out to GDE FIFO and SLINK at 78MHz on a common bus, 64-bits wide (plus control signals).
- 80.00 MHz PECL on-board; drives a 1-5 PECL clock driver. 4 outputs to the InCtrl FPGAs & 1 output to VMEctrl, 1 load each.
- 62.5 MHz LVTTL on-board; goes only to DDUctrl for GbE control
- 40.08 MHz LVTTL LHC clock from TTC via DCC/backplane connection; DDUctrl FPGA serves as 1-4 clock driver w/1-output per FPGA (includes a self-feedback), 1 load each.
- 10 MHz LVTTL SCLK (Serial/Slow Clock); derived from 80 MHz clock by DCM inside VMEctrl FPGA and fanned-out to All Other FPGAs and serial devices on a common bus (7 loads) with termination. Requires 24 mA IO drive setting.

FPGAs

- XC2VP20 "InCtrl FPGAs" (need 2 for Input Control, use 240+ IO each)
 -use FG676 package (404 I/O), -6 speed grade (faster -7 costs more)
 -TWO linked XC18V04 PROMs used to program both FPGAs in parallel
 ---> both InCtrl FPGAs use identical Firmware
 - -8 IO: use parallel load DIN[7:0] and CCLK line w/linked DONE pins -set one FPGA as SelectMAP Master, other as SelectMAP Slave
 - ---> SelectMAP Master provides program clock CCLK
 - -each FPGA uses 7-8 Rocket IO to read in 7-8 DMB fibers
 - -JTAG is used for all PROM programming via the VME FPGA; JTAG is available on all FPGAs for slow control
 - -Main Clock is 80.00 MHz DMB-DDU-matched oscillator (fanout from PECL clock driver)
 - ---> drives 2 differential input pairs on InCtrl FPGA (4 BREF IO, not BREF2) for Fiber Reference clocks (1 Top edge, 1 Bottom edge) as well as logic clocks (via BUFG) and GT USRCLKS (GT is Gigabit Transceiver logic module from Virtex2 library)

Each InCtrl FPGA is functionally split into a "top half" and a "bottom half", each responsible for processing the data from the 4 top-edge RocketIO and 4 bottom-edge RocketIO respectively. Each half-FPGA has the following functions (see file ddu_in.pdf for logic schematics):

- -44 Block RAMs configured as 22 FIFO MemUnits, 4 kB each, which are assigned to the RocketIO on an as-needed basis. In this way, any RocketIO that need more storage may be allotted any combination of the 22 MemUnits as they are available.
- -A MemControl Unit to control assignment of the BRAM FIFOs. There is a priority alogorithm to select the assignments preferentially.
- -4 InUnits, each containing one RocketIO, a buffer to record MemUnits in use, and data monitoring logic. This logic watches for Status Codes sent from the DMBs and flags & corrects any 64-bit word boundary violations that occur. InUnits can also transmit data via fiber to any selected DMBs via a common data bus from the DDUctrl FPGA. Before the MemUnit in use becomes full, the InUnit will request another from MemCtrl and then switch to the new unit when the current one goes Full. InUnits will "free" a MemUnit for reuse when it goes Empty. Each InUnit has a 4-bit path to the VMEctrl FPGA to report status information.
- -A ReadControl Unit that writes exclsively to one on-board DDR FIFO (0.5 MB external storage unit). The RdCtrl gets the data from each RocketIO and checks L1A numbers for an event.as the data is read out. RdCtrl forwards the Kill signal from DDUctrl to appropriate RocketIOs and watches for timeouts or changes in the link status of the InUnits. It also monitors the AlmostFull/Full status of the external DDR FIFO and the internal MemCtrl, then sends out a Warning (to TTS) or Busy/Stop signal (to TTS & DMBs respectively) as needed. The event number and a summary of all the checks done within InCtrl are sent out to the FIFO as the last word an event; this information will be assimilated in the DDUctrl FPGA. Each RdCtrl has a 4-bit path to the DDUctrl FPGA to report its operating conditions.

Both halves of the InCtrl FPGA share a common JTAG control unit. This is used primarily as an interactive monitoring/debug tool.

```
>>>InCtrl FPGA IO on-board hardware connections (for one chip):
                                                                                   -sends data to the external GbE FIFO on a prescalable basis
        4 dedicated input lines (2 pairs) from PECL clock driver
                                                                                   -creates & transmits GbE packets from data stored in external GbE FIFO
                                                                                   -reads Board ID & Killed Channel constants from Flash RAM and sends
        2 global Reset inputs (from DDUctrl)
       1 LVTTL clock input (SCLK) from VMEctrl
                                                                                       Kill Channel signals to InCtrl FPGAs
        50 dedicated lines for IDT DDR FIFOs (44 Out, 6 In)
                                                                                   -controls a 16-bit data bus to send control or data signals out on any
        32 configurable IO to VMEctrl FPGA
                                                                                       Fiber via InCtrl FPGAs
        56 configurable IO to DDUctrl FPGA
                                                                                   -monitors the DDU Board Operation condition, summarizing the 4 RdCtrl
        24 IO for Fiber support (3 per fiber)
                                                                                       and the DDUctrl status on one 4-bit path to the VMEctrl FPGA
        70 Other IO, 12 required for parallel PROM load and INIT signals
            ---> optional 8 input from switches, 8 output to LEDs
                                                                                 >>>DDUctrl FPGA IO on-board hardware connections:
            ---> optional 42 IO for header/testpoints for InCtrl FPGA#0
                                                                                       3 dedicated input lines from PECL/LVTTL sources
            ---> optional 6 IO for testpoints for InCtrl FPGA#1
                                                                                       1 LVTTL clock input (SCLK) from VMEctrl
                                                                                       2 IO for local 78 MHz LVTTL clock feedback
        64 additional signals for RocketIO (8 per RocketIO)
        1 signal to specify chip as InCtrl FPGA#0 or #1
                                                                                       2 global resets Out (Sync & Soft reset)
                                                                                       18 control lines from TTC (15), DCC (2) & VME (1)
  >>>How exactly do we use these IO in the DDU InCtrl?
                                                                                       75 dedicated lines for IDT DDR FIFOs (40 data, 35 control)
    -100+ IO; each InCtrl FPGA uses these signals:
                                                                                       91 configurable IO to InCtrl FPGA
        80MHz Main Clock (4 IO), 40MHz LHC Clock (from DCC via DDUctrl
                                                                                       16 configurable IO to VMEctrl FPGA
           FPGA), 10MHz SlowCLK from VMEctrl (1 IO)
                                                                                       116 IO for SLINK & GbE
        5-bits from DDUCtrl: L1A, EvCntRst, L1RST, SoftReset, BC0/BXR
                                                                                            ---> Min. 83 for SLINK; 33 more are for GbE only.
        10-bits to/from DDUCtrl FPGA as spare (include 1 clock I/O pin)
                                                                                       64 Other IO, 12 required for parallel PROM load and INIT signals
        16-bits input data from DDUCtrl for TxData to DMB (via Rocket IO)
                                                                                            ---> optional 8 input from switches, 8 PROM lines go to LEDs
       1 DLL Lock/Ready (to DDUctrl), 2 FIFO_Active (1 per RdCtrl)
                                                                                            ---> optional 43 IO to header/testpoints, 1 pushbutton switch
        4 control/IO signals left free: INIT, CS, WRITE, DOUT (Don't Use)
                                                                                       24 additional signals for RocketIO (8 per RocketIO)
        2 * 20-bit DOUT to FIFOs (bits 16-19 flag Fill, LW, Hdr, Tr resp.)
        2 * 5-bit FIFO control: WCLK, ~WEN, ~PAE, ~PAF, FF
                                                                                 >>>How exactly do we use these IO in DDUctrl?
        2 * 4-bit FPGA status bits (to DDUctrl, 1 4-bit set per RdCtrl)
                                                                                   -7 IO used for 4 ext. CLKs for DDUctrl: Main Clock (156 MHz) MUST use
    -72 IO; need per Rocket IO used on each FPGA (multiply below by 8):
                                                                                          LVDS IO (IBUFGDS) & divide-by-2 for 78 MHz, one 62.5 MHz for
        2-bits for Tx control from DDUctrl FPGA: TxEn, Kill Fiber
                                                                                          GBE, 40.08 MHz LHC clock, 10 MHz serial shift clock (SCLK)
        3-bits for Fiber/FIFO Status: FOK (in), FOKout, DAV (to FP-LEDs)
                                                                                           ---> 80 MHz feedback LVTTL goes out * back for DCM lock (2 IO)
        4 for DMB status: T[3:0] for FMM (to VMEctrl)
                                                                                   -18 IO; DDU board control
    -58 IO; added header connectors for 2 Logic Analyzer (LA) ports (18
                                                                                       1 pushbutton input (debounced, goes to DDUctrl) used for logic RST
                                                                                       1 SYSRESET input from VME, [+4 JTAG lines]
       bits each, only InCtrl FPGA#0), 6 testpoints, 8 LEDs, 8 switches
    -8 IO dedicated for parallel PROM load
                                                                                       3 DLL-Lock signals (1 from each FPGA, tells DDUctrl they're ready)
    -InCtrl FPGA#1 "kills" RocketIO #6 (the 16th RocketIO) as it is unused
                                                                                       4 FIFO Active (1 per RdCtrl from InCtrl FPGAs)
                                                                                       5-bits control Output from DDUctrl, common for other FPGAs:
                                                                                          LlAout, EvCntRst, LlRST(SyncRst), SoftReset, BC0/BXR
                                                                                        4 control/IO signals left free: CS, WRITE, DOUT, INIT (Don't Use)
XC2VP7 "DDUctrl FPGA" (uses 388+ I/O)
                                                                                   -30 IO; each InCtrl Rocket IO has individual control (below times 15):
    -use FF672 package (396 I/O), requires -6 speed grade or faster (-7)
                                                                                       Enable (for TxEn), Kill (for Rx/Tx)
                                                                                   -16-bit output for DMB Tx data bus (parallel to both InCtrl FPGAs)
    with flip-chip package
                                                                                   -16 status bits from InCtrl FPGAs (4-bits from each RdCtrl)
    -TWO linked XC18V04 PROMs, use parallel load DIN[7:0] and CCLK lines
        ---> use SelectMAP Master mode for program clock, FPGA drives CCLK
                                                                                   -20 bits from/to InCtrl FPGAs as spare (10 each, inc. 1 clock I/O pin)
    -2 Rocket IO to backplane (data to DCC via HSC connector, 3.2 Gb/s)
                                                                                   -41 IO; 1 40-bit input data bus to read 4 FIFOs at DDR,
    -1 Rocket IO to front panel output Ethernet fiber (1.25 Gb/s)
                                                                                          plus 1 common RCLK shared by all DDR FIFOs (4 loads)
                                                                                   -32 IO; each DDR FIFO has individual controls (multiply by 4 below):
  The DDUctrl FPGA reads in data from the 4 on-board DDR FIFOs, 1 event at
                                                                                          ~OE, ~REN, MT, ~PAF, FF, ~EREN; also Mark, ~RT
  a time. Each event is checked for the following during readout:
                                                                                   -2 IO; common FIFO control (for all IDT FIFOs):
    -improper event formatting & data corruption
                                                                                           ~MRST/~TRST (after soft reset), ~PRST (after sync/logic reset)
    -status/error flags passed from InCtrl via DDR FIFO
                                                                                   -16 IO; control input from TTC/DCC
    -event & bunch number synchronization from each source
                                                                                        cmd_bus[8:0], L1A, Link Ready/Full, plus 4 others
    -CFEB wordcount & CRC from each source
                                                                                   -66-bit output data (to GbE FIFO/SLINK)
   -TMB wordcount & CRC from each source
                                                                                   -18-bit input data from GbE FIFO (for GbE packets out via RocketIO)
    -ALCT wordcount & CRC from each source
                                                                                   -14 IO; GbE FIFO control (SDR IDT Terasync):
   -missing DMB, CFEB, TMB or ALCT data from each source
                                                                                           WCLK, RCLK, WEN, REN, FF, ~PAF, ~PAE, MT, ~HF
    -timeout conditions
                                                                                           Output fiber FOK, FOKout LED, DataValid LED. Also Mark, ~RT.
 DDUctrl performs the following tasks (see logic schematics in ddu_ctrl.p
                                                                                   -18 IO; SLINK control
                                                                                       10 Inputs: LFF, LDOWN, LRL[3:0], LSF[3:0]
                                                                                       8 Outputs: UWEN, UCTRL, URST, UTEST, USF[3:0]
    -event readout, processing and monitoring
                                                                                   -15 IO; communication to/from VMEctrl
   -receives & decodes TTC Command Bus instructions from DCC (via
        backplane); e.g. BCO, Sync/Soft Reset, Start/Stop data taking
                                                                                       4 FMM bits to VMEctrl
    -receives & distributes CMS Clock & L1A from TTC/DCC to other FPGAs
                                                                                       4 FMM bits from VMEctrl (also go to FMM cable)
    -watches for changes in status of the RdCtrl units
                                                                                       2 control bits for SLoad, SData input from VMEctrl
    -monitors the status feedback from the DCC/SLINK paths and Stops DDR
                                                                                          -from serial-flash memory for "kill" fiber [16],
       FIFO readout as needed
                                                                                           Board ID [32], etc.
    -adds event information in the headers and trailers, conforming to CMS
                                                                                       5 bits from/to VMEctrl FPGA as spare (includes 1 clock I/O pin)
       Common Data Format rules
                                                                                   -59 other IO; 8 switches, 8 LEDs (share PROM DIN), 2 LA Ports (36 IO),
    -generates a CRC word for all data transmitted for the event
                                                                                       7 extra IO to "test points"
    -sends all data out via DCC/SLINK paths
```

```
Output FIFO: use IDT 72T72115L5,6-7 (324 PBGA SDR 128K x 72-bits, 72/72)
XC2V500-5FG456c "VMEctrl FPGA" (uses 254 IO, 264 available)
                                                                                    -use 66-bits In (78MHz), 18-bits Out (62.5MHz), all at SDR
   -One XC18V04 PROM, use parallel load DIN[7:0] and CCLK lines
                                                                             Serial Flash RAM: use 1 AT45DB011B (over 1 Mb, 8-pin SOIC), 20 MHz max.
       ---> use SelectMAP Master mode for program clock
                                                                                    -uses 10 MHz derived from SCLK; can do 20 MHz, but the IDT FIFOs
   -Program VME PROM from VME FPGA, JTAG cable or Discrete on-board
                                                                                       serial clock is limited to 10 MHz max.
       VME Logic; uses parallel load DIN[7:0] and CCLK lines to FPGA
                                                                                    -stores constants in Pages for DDU Board ID, Killed channels, etc.
    -Main Clock is 80.00 MHz DMB-DDU-matched oscillator (fanout from PECL
                                                                                  Useful OpCodes: d2h, d7h, 82h
                                                                                    -all constants only use ~100 bits of memory; over 1 Mb is available
                                                                                      for additional constants if desired
 VMEctrl performs the following tasks (see logic schematics in ddu_vme.pd
                                                                                  Use Block0: page1=KillCh (16b),
                                                                                                                          page7=BoardID (8b),
                                                                                             page4=DDR FIFO Thresh (32b), page5=GbE FIFO Thresh (34b)
    -decodes VME Bus signals into on-board Parallel, Serial and JTAG paths
   -controls all Read and Write functions for the on-board 1 Mb Serial
       Flash RAM; constants are read out and sent to the appropriate
                                                                             Other Notes
       devices after every Soft Reset
    -continually receives 4-bit status summaries from DDUctrl and 15 fiber
                                                                             Hard_Reset has 3 sources logical OR'ed together w/discrete on-board logic:
       sources, uses this to determine the instantaneous status of the
                                                                                -TTC via DCC/Backplane connection
                                                                                 -Power-On sensor
       entire 20-degree DDU Sector, sending the result to TTS via FMM
                                                                                 -PROGRAM button input (debounced)
 >>>VMEctrl FPGA IO on-board hardware connections:
                                                                                Hard Reset goes to all FPGA PROGRAM pins.
       2 dedicated clock input lines from PECL clock driver
                                                                             The 2nd on-board pushbutton (debounced) makes a Soft Reset in DDUctrl,
        2 global resets In (Sync & Soft reset from DDUctrl)
                                                                                which fans it out to other FPGAs, and sends sync'd MRST to all IDT
       11 configurable IO to DDUctrl FPGA
                                                                                FIFOs. (This could be reconfigured for another purpose as needed.)
        60 configurable IO from InCtrl FPGA
                                                                                 -DDUctrl also sets the LD & FWFT/SI signals in time with the MRST
        64 dedicated lines for VME Backplane IO
                                                                                 -MRST is tied to the FIFO TRST lines (JTAG reset)
                                                                             The board has discrete "Emergency VME-Recovery" logic on board to allow
       4 dedicated output lines to RJ45 for FMM/TTS; LVTTL-LVDS
                                                                                for bootstrap VMEctrl PROM programming. There is also a 10-pin JTAG
          conversion done on-board
        30 IO for 8 JTAG paths (for FPGAs, PROMs & FIFOs)
                                                                                header connector for programming this PROM via laptop if desired. All
        20 IO for other Serial controls (FIFO thresholds, etc. from SRAM)
                                                                                other PROMs _must_ be programmed via VME, with no alternative provided.
       61 Other IO, 12 required for parallel PROM load and INIT signals
           ---> optional 8 input from switches, 8 PROM lines go to LEDs
           ---> optional 41 IO for header/testpoints
                                                                             ______
  >>>How exactly do we use these IO in VMEctrl?
                                                                              The 3 sections below are the UCF files containing the Location and Timing
   -45 VME input IO: ADR[23:1], AM[5:0], GA[5:0],
                                                                              Constraints for all FPGA firmware.
       sysreset, sysfail, clk, write, iack, lword, berr, as, ds0, ds1
                                                                             ______
   -19 VME output IO: dtack, ToVME, doe, D[15:0]
   -68 FMM IO: 4-bit FMM output (to DDUctrl [TTL] and FMM cable [LVDS])
                                                                             DDU InCtrl FPGA UCF file
       60-bit DMB status inputs (15 DMBs * 4 bits each from InCtrl FPGAs)
       4-bit DDUctrl status inputs
                                                                             ______
                                                                             # use with "D785D: IN_CTRL" Logic schematic
   -9 control IO
        80 MHz PECL clock, 2 global Reset inputs (from DDUctrl)
       1 DLL Lock/Ready (to DDUctrl)
                                                                             #PINLOCK BEGIN
       4 control/IO signals left free: CS, WRITE, DOUT, INIT
                                                                             #Wed Nov 24 14:17:16 2004
    -21 Serial control IO (for 4 Input FIFOs, 1 Output FIFO, 1 DDUctrl)
                                                                             #INPUTS
        Common SCLK (8 loads), SData (6 loads)
                                                                             # Clock & Control signals in:
        4* ~SREN, 4* ~SWEN, 4* SDback (readback path from In FIFOs)
                                                                             # from switches (added 4)
       6 bits for FlashMemory Control (M_SCLK, SI, SO, ~CS, ~WP, ~RESET)
                                                                             NET "$11162/~SOFTRST" LOC = "AB4";
                                                                             NET "$1I162/EV_RST" LOC = "AB1"; #l1arst
       1 Serial Enable bits to DDUctrl
                                                                             NET "$1I162/~L1RST" LOC = "AA5"; #syncrst
    -5 spare signals to DDUctrl FPGA
                                                                                                  LOC = ""; # not used
    -30 IO for 8 JTAG paths (4 IO each):
                                                                             #NET "$11162/BXRIN"
       1.5 for DDUctrl PROM and FPGA (path 6 & 8 share TMS6 & TCK6)
                                                                             #NET "$11162/BX0IN"
                                                                                                 LOC = "AB2"; #input for bc0out, not used yet
                                                                             NET "$1I162/MODEIN7" LOC = "H6";
       1 for VMEctrl PROM (program by VMEctrl, VME-Recovery & JTAG cable)

```
Component coordinate ranges:
                SLICE x0y0 to x91y111
                TBUF x0y0 to x90y111, even x only
                RAMB16 x0y0 to x7y13 (88 total)
                      x0y0 to x3y1 (8 total)
                      x0y0 to x3y1 (8 total)
                MULT18X18 x0y0 to x7y13 (88 total)
# In GRID Coords (X,Y) bottom left is X3Y4, top right is X138Y227
       X value cycles through SLICE-TBUF-SPECIAL with increasing X
                -X3Y4 is a SLICE, so is X138Y227
                -SPECIAL is RAMB/MULT or GT or DCM
                -SPECIAL only exists at X=8,26,44,62,80,98,116,134
                  RAMB/MULT exist at all these X locations
                   GTs at X=26,62,80,116 .and. Y=19,227
                  DCMs at X=8,44,98,134 .and. Y=3,231
       Y values are continuous for Slices, except for PPC holes
               -TBUFs are only even in Y (2 per CLB)
                -RAMBs are spaced 16 apart in Y,
                  starting at Y=35 on GT columns, Y=19 otherwise
                   (GTs effectively take up a RAMB spot)
                -MULTs are 1 lower in Y than RAMB (at Y_RAMB - 1)
# PPC "Dead Zone" holes:
     No TBUFS from x14y40 to x58y71 .and. x62y40 to x76y71
            GRID: X23Y88 to X47Y143 .and. X95Y88 to X119Y143
